## Content

1. Introduction: Some facts on polarization in comets
2. Modeling of light scattering by cometary dust particles
3. Cometary dust as seen from its negative polarization
4. Cometary dust as seen from its positive polarization
5. Estimation of the geometric albedo with the Umov effect
6. Summary

# 1. Some facts on polarization in comets

# Why Polarization?

A convenient way to describe interaction of light with some target is to use formalism of **Stokes vectors** and **Mueller matrices**. Stokes vector is a four-dimension vector that is defined as follows:

$$\mathbf{S} = \begin{pmatrix} I \\ Q \\ U \\ V \end{pmatrix}$$

Stokes vectors are defined in reference to **the scattering plane**, which is determined by locations of source of light (the Sun), target (Comet), and detector of light (Telescope)

Using Stokes vectors one can easily express **unpolarized light**  
 $\mathbf{S}=[I,0,0,0]^T$

# Why Polarization?

If the light is characterized with Stokes vectors, then, interaction of light with a target can be expressed with a 4x4 Mueller matrix:

$$\mathbf{M} = \frac{1}{(kR)^2} \begin{pmatrix} M_{11} & M_{12} & M_{13} & M_{14} \\ M_{21} & M_{22} & M_{23} & M_{24} \\ M_{31} & M_{32} & M_{33} & M_{34} \\ M_{41} & M_{42} & M_{43} & M_{44} \end{pmatrix}$$

However, if target particles are randomly oriented, Mueller matrix is reduced as follows:

$$\mathbf{M} = \frac{1}{(kR)^2} \begin{pmatrix} M_{11} & M_{12} & 0 & 0 \\ M_{12} & M_{22} & 0 & 0 \\ 0 & 0 & M_{33} & M_{34} \\ 0 & 0 & -M_{34} & M_{44} \end{pmatrix}$$

# Why Polarization?

Interaction of the sun-light with cometary dust particles yields:

$$\mathbf{S}^{Obs} = \mathbf{M}^{Comet} \times \mathbf{S}^{Sun} = \frac{1}{(kR)^2} \begin{pmatrix} M_{11} & M_{12} & 0 & 0 \\ M_{12} & M_{22} & 0 & 0 \\ 0 & 0 & M_{33} & M_{34} \\ 0 & 0 & -M_{34} & M_{44} \end{pmatrix} \times \begin{pmatrix} I \\ 0 \\ 0 \\ 0 \end{pmatrix} = \frac{I}{(kR)^2} \begin{pmatrix} M_{11} \\ M_{12} \\ 0 \\ 0 \end{pmatrix}$$

Only  $I$  and  $Q$  elements in Stokes vector of the scattered light are non-zero.

Element  $Q$  exceeds  $U$  and  $V$  for at least two orders of magnitude.

Here, we focus on the degree of linear polarization  $P$ :

$$P = -\frac{Q}{I} \times 100\% = -\frac{M_{12}}{M_{11}} \times 100\% = \frac{I_{\perp} - I_{\parallel}}{I_{\perp} + I_{\parallel}} \times 100\%$$

6

$P$  in comets varies with phase angle  $\alpha$

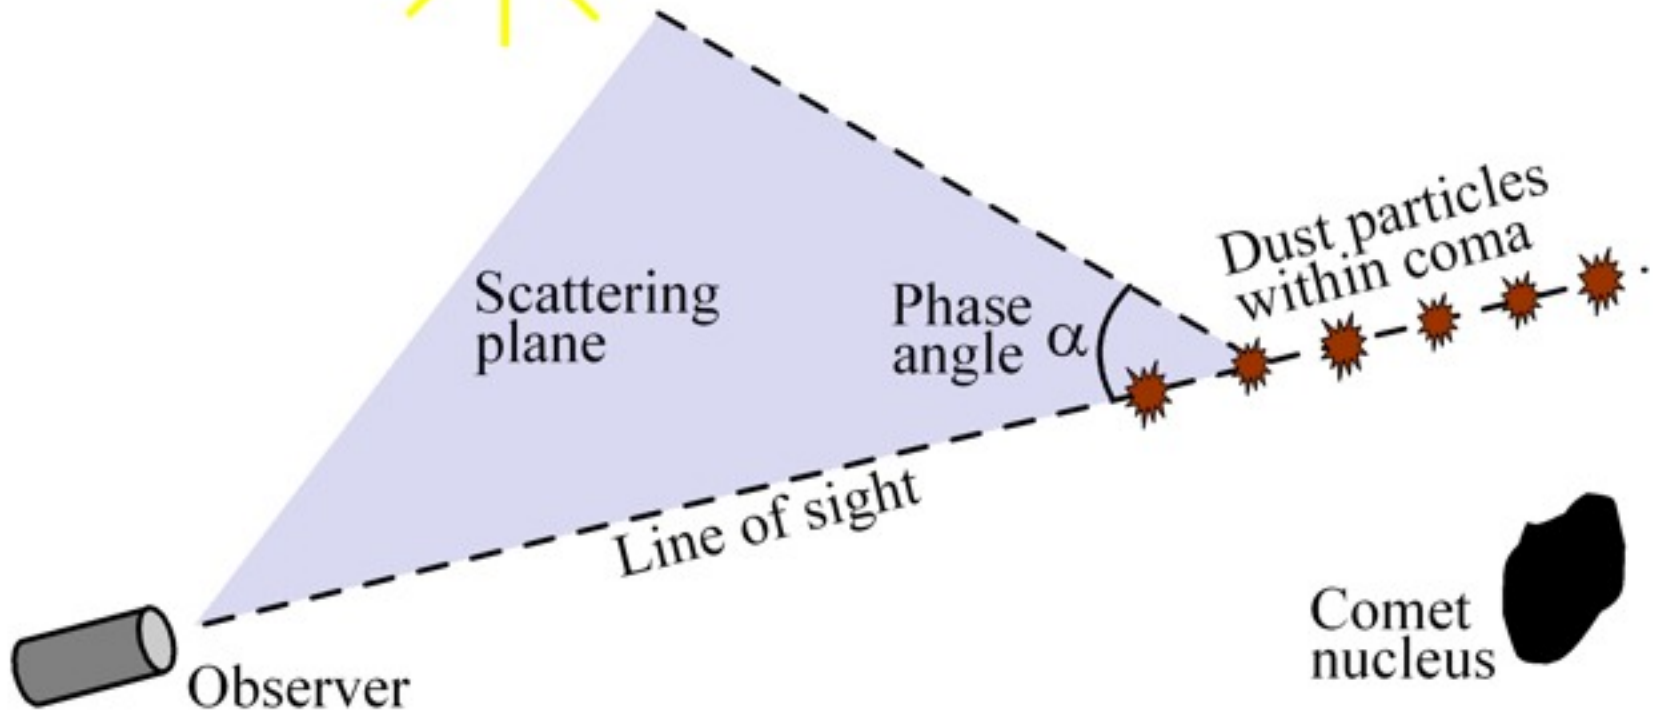

$$P = \frac{I_{\perp} - I_{\parallel}}{I_{\perp} + I_{\parallel}}$$

the Sun

$$P > 0 \text{ if } I_{\perp} > I_{\parallel}$$

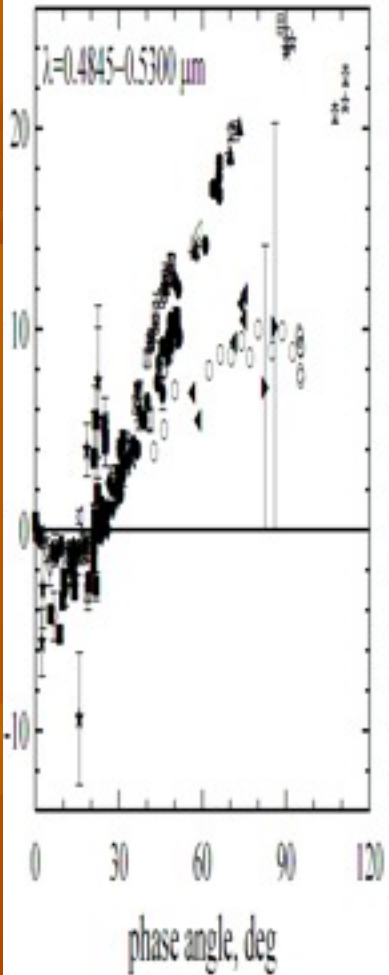

$$P < 0 \text{ if } I_{\perp} < I_{\parallel}$$

# Aperture-averaged $P$ in comets

Typical angular profile of  $P$  measured in whole comets:

Principal characteristics

$$P_{\min} \approx -1.7\%$$

$$\alpha_{\min} \approx 10-11^\circ$$

$$P_{\max} \approx 10-30\%$$

$$\alpha_{\max} \approx 90-100^\circ$$

Cumulative characteristics

$$h \text{ and } \alpha_{\text{inv}}$$

# Spatially resolved polarimetry of comets

However,  $P$  is a **time-varying** characteristic; it depends on **wavelength  $\lambda$**  and varies **throughout entire coma**.

$R=4.2$  AU

$R=1.8$  AU

$R=1.6$  AU

38000 km

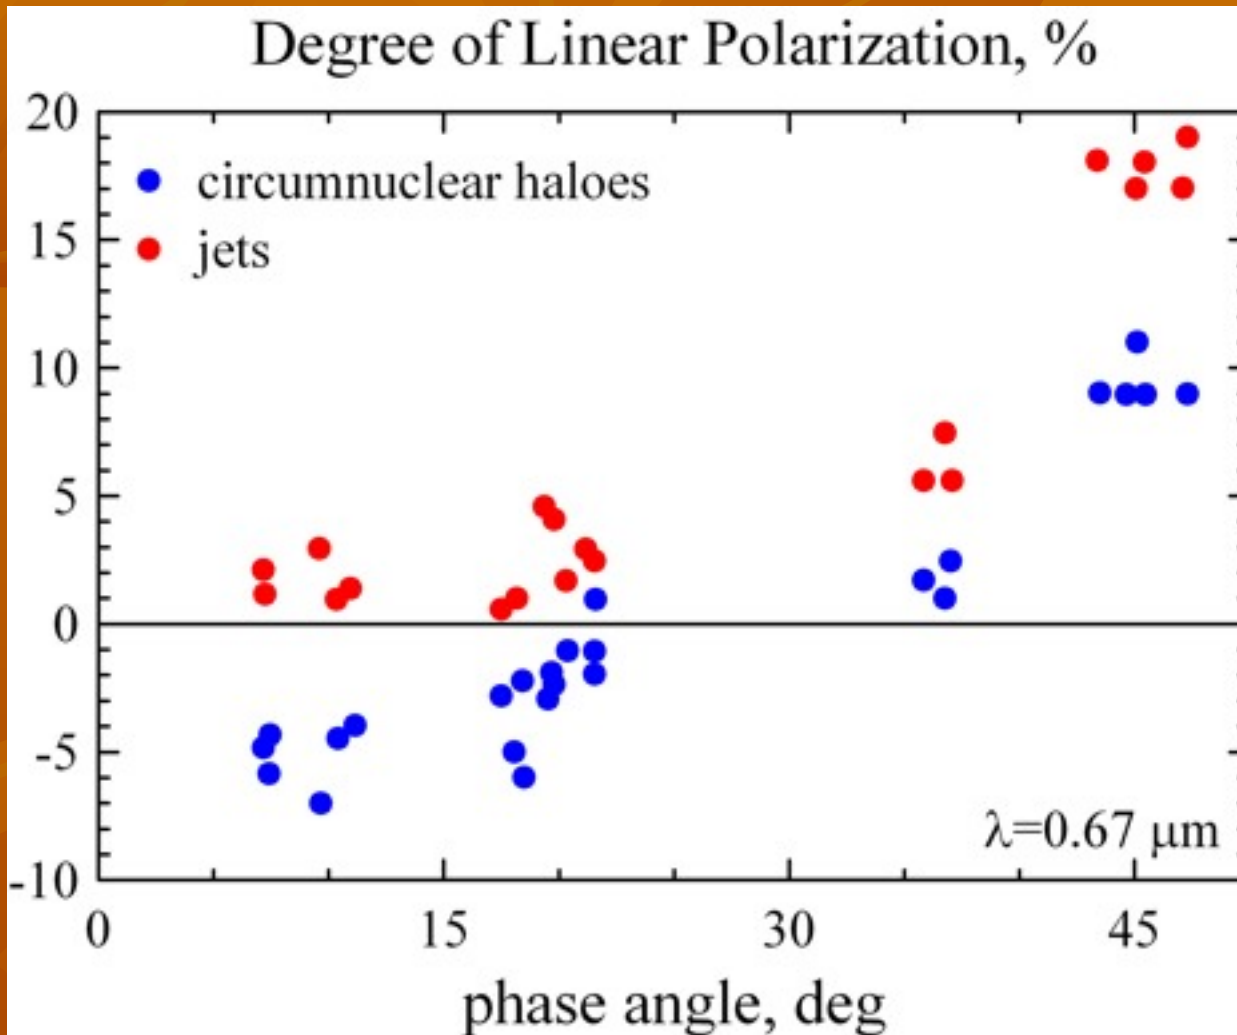

9000 km

4400 km

Hadamcik & Levasseur-Regourd, 2003

# Spatially resolved polarimetry of comets

Two noticeable features in a coma:

## Circumnuclear Halo

$$P_{\min} = -6\%$$

$$\alpha_{\min} = 15^\circ$$

$$P_{\max} < 10\% (?)$$

$$\alpha_{\max} < 90^\circ (?)$$

## Jets

$$P_{\min} = 0\%$$

$$\alpha_{\min} = 0^\circ$$

$$P_{\max} > 30\%$$

$$\alpha_{\max} > 90^\circ (?)$$

Hadamcik & Levasseur-Regourd, 2003

The background of the slide is a solid orange color with a pattern of stylized, overlapping leaf shapes in a slightly darker shade of orange. The leaves are scattered across the frame, creating a textured, organic feel.

## 2. Modeling of light scattering by cometary dust particles

# Simulation of light scattering

We compute light scattering by micron-sized particles using the **discrete dipole approximation (DDA)**

Concept:

**Advantages:**

- (1) arbitrary shape and internal structure
- (2) simplicity in preparation of sample particles

**Penalty:**

long computations

# Simulation of light scattering

## Modeling cometary dust particles

Initial matrix is divided for **surface layer** and **internal volume**.

Parameters for **surface layer**:

- (1) depth;
- (2) number of seeds for empty space.

Parameters for **internal volume**:

- (1) number of seeds for a material;
- (2) number of seeds for empty space.

# Simulation of light scattering

Other parameters of light scattering by small particles

(1) *size parameter*  $x = 2\pi r/\lambda$  ( $r$  – radius of circumscribing sphere and  $\lambda$  – wavelength).

In most cases,  $x$  varies from 1 throughout 24-40

(2) *complex refractive index*  $m$  (it relates chemical and mineral composition of the given material with its ability to scatter and absorb light)

Agglomerated debris particles are considered at 27(!)  
various  $m$ :

1.1+0*i*, 1.2+0*i*, 1.313+0*i*, 1.313+0.02*i*, 1.313+0.05*i*,  
1.313+0.1*i*, 1.4+0*i*, 1.4+0.02*i*, 1.4+0.05*i*, 1.4+0.1*i*, 1.5+0*i*,  
1.5+0.02*i*, 1.5+0.05*i*, 1.5+0.1*i*, 1.6+0.0005*i*, 1.6+0.01*i*,  
1.6+0.02*i*, 1.6+0.05*i*, 1.6+0.1*i*, 1.6+0.15*i*, 1.7+0*i*,  
1.7+0.02*i*, 1.7+0.05*i*, 1.7+0.1*i*, 1.758+0.0844*i*,  
1.855+0.45*i*, 2.43+0.59*i*

# Simulation of light scattering

Averaging:

(1) **over 500+ random shapes.**

In addition, light-scattering properties of each particle are averaged over 100 azimuthal orientations (i.e., particle is rotated around direction of the incident light propagation). Standard deviation of the degree of linear polarization  $P$  does not exceed 1% throughout all phase angles.

(2) **over particle sizes with power-law size distribution**

$$r^{-a}.$$

The power index  $a$  is varied from 1.5 to 3.5.

Such size distribution is well consistent with *in situ* study of comet 1P/Halley (e.g., Mazets et al., 1986)

### 3. Cometary dust as seen from its negative polarization

# Negative polarization for various $\text{Re}(m)$

Increase of  $\text{Re}(m)$ :

(1) does not affect amplitude in function  $P_{\min}$  vs.  $x$

(2) shifts maximum in function  $P_{\min}$  vs.  $x$  toward smaller  $x$

# Negative polarization for various $\text{Im}(m)$

Increase of  $\text{Im}(m)$ :

(1) decreases substantially  $P_{\min}$

(2) does not affect location of maximum in function  $P_{\min}^{20}$  vs.  $x$

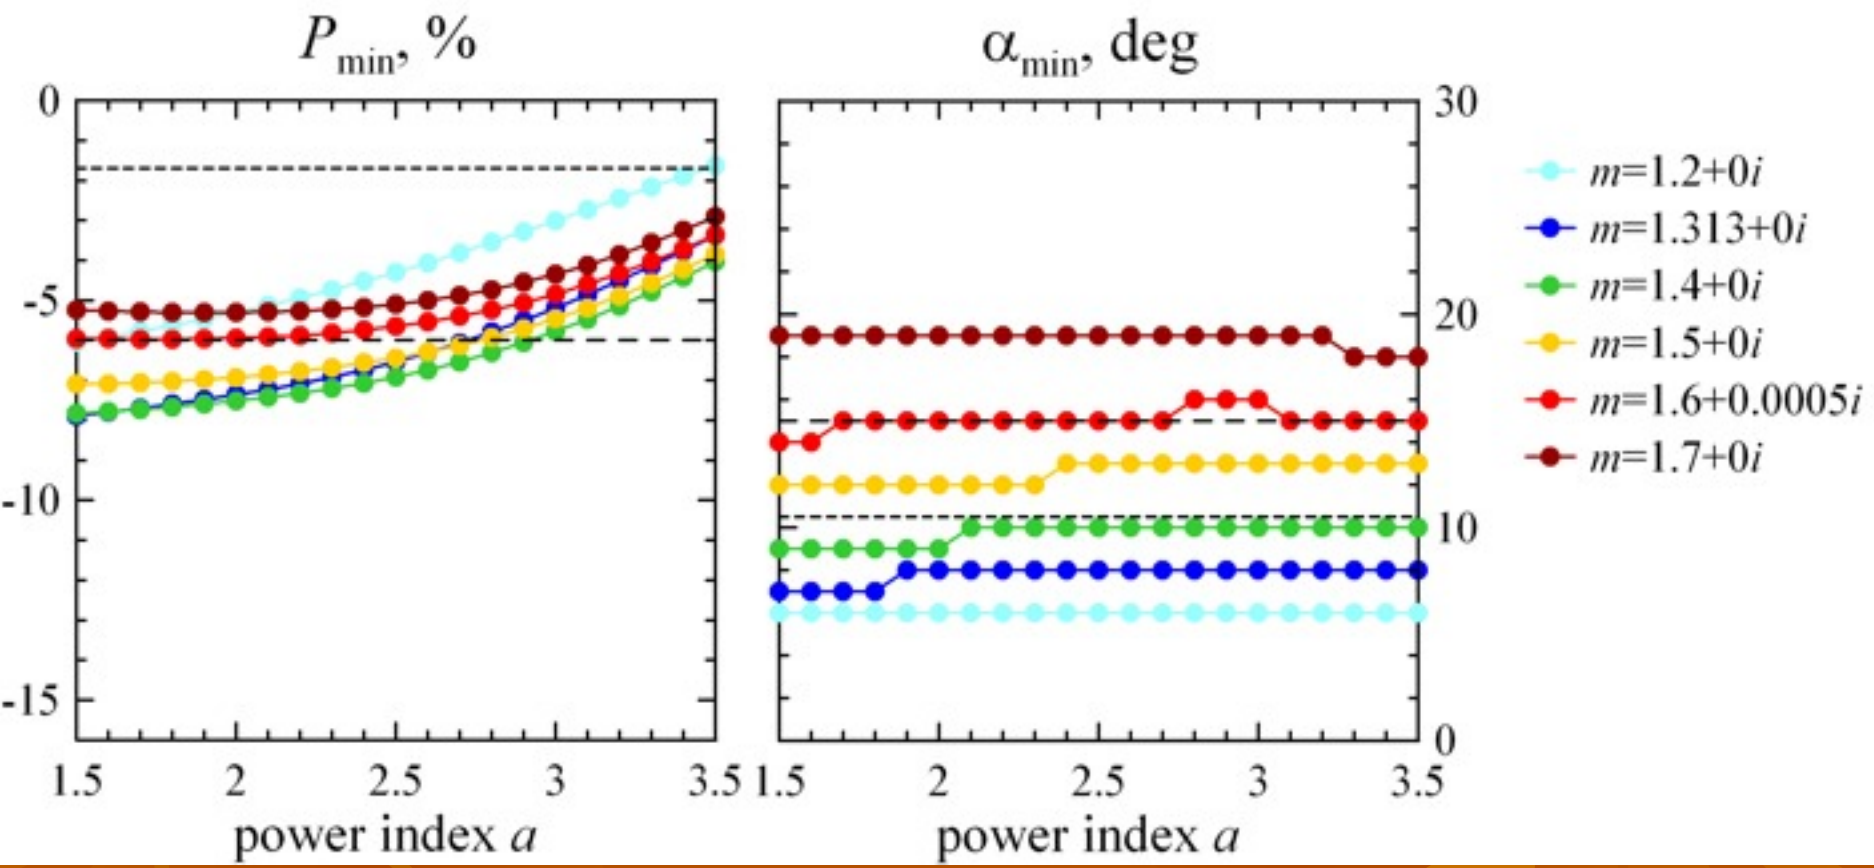

# Negative polarization for various $\text{Im}(m)$

Highly absorbing ( $\text{Im}(m) \geq 0.15$ ) carbon-rich materials cannot reproduce the negative polarization measured from a whole cometary coma because  $P_{\min} \approx 0$  throughout all  $x$ .

# Negative polarization for various $\text{Re}(m)$

## Size-averaging:

- (1) substantially dampens  $P_{\min}$  as compared to that for fixed size
- (2) makes  $\alpha_{\min}$  an extremely stable

# Negative polarization for various $\text{Im}(m)$

Size-averaging constrains absorption of cometary materials:

- (1) in cometary haloes  $\text{Im}(m) \leq 0.02$
- (2) in whole coma  $\text{Im}(m) \leq 0.07 - 0.08$

# Negative polarization vs. morphology at $m=1.313+0i$

Particle morphology does not affect the negative polarization significantly.

# Negative polarization vs. morphology at $m=1.6+0.0005i$

Particle morphology does affect  $P_{\min}$  at  $a < 2.5$ . It is comparable with accuracy in polarimetry of comets (i.e.,  $\pm 1\%$ ). The impact of the morphology on  $P_{\min}$  is much less than that of absorption.

# Negative polarization vs. morphology at $m=1.5+0.1i$

Particle morphology does not affect the negative polarization significantly.

# Summary on the negative polarization

1. The negative polarization produced by single-scattering irregularly shaped particles is unambiguously dependent on  $\text{Im}(m)$ . It can be used to determine local excess for Mg-rich silicates and carbonaceous materials in a cometary coma.
2. The index  $a$  in power-law size distribution may also affect considerably the negative polarization. However, its solely variation cannot explain dramatic difference in negative polarization of *whole coma*, *circumnucleus halo*, and *jets*.
3. True morphology of irregular agglomerates produces only minor impact on the negative polarization. It is typically less than the accuracy in polarimetric observations of comets.

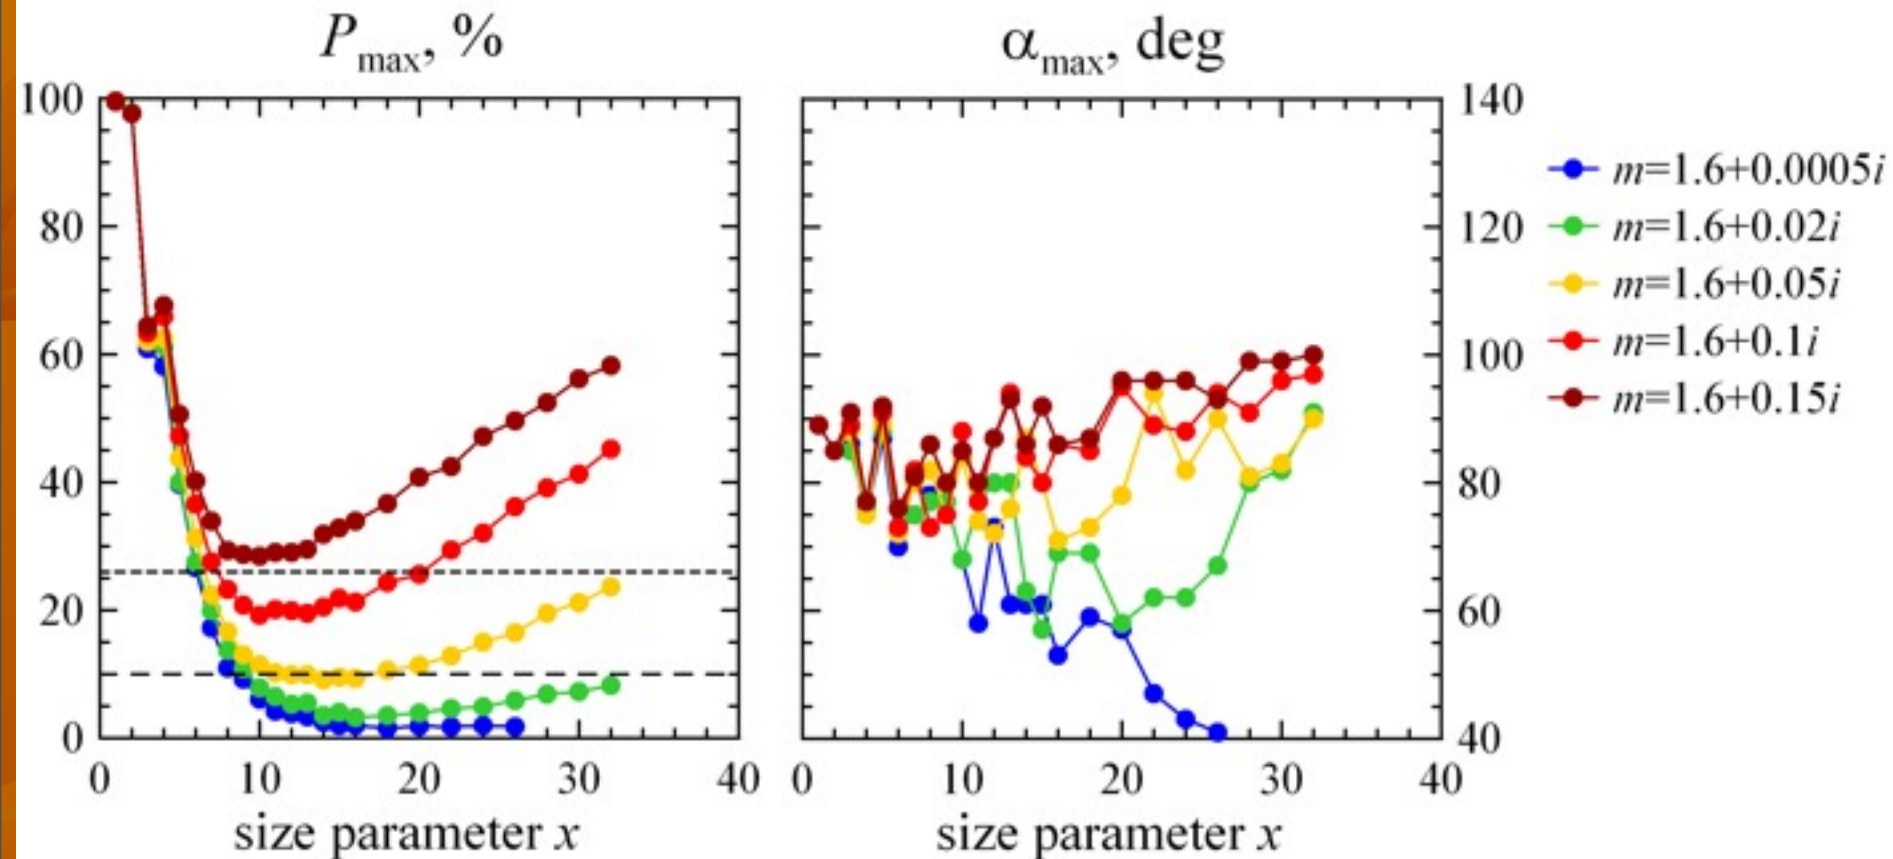

## 4. Cometary dust as seen from its positive polarization

# Positive polarization for various $\text{Re}(m)$

Increase of  $\text{Re}(m)$  dramatically decreases the amplitude of positive polarization  $P_{\max}$ .

# Positive polarization for various $\text{Im}(m)$

Increase of absorption substantially increases  $P_{\max}$ . It also makes a non-monotonic behavior in function  $P_{\max}$  vs.  $x$ ; whereas, lowest value of  $P_{\max}$  is achieved at  $x=10-16$ .

# Positive polarization for various $\text{Re}(m)$

Size-averaging constrains the refractive index of cometary materials. Whole-coma  $P_{\max}$  cannot be reproduced with optically soft materials at  $\text{Re}(m) < 1.3$ .

# Positive polarization for various $\text{Im}(m)$

Size-averaging constrains the material absorption in comets. Whole-coma  $P_{\max}$  cannot be obtained at  $\text{Im}(m) \geq 0.1$ . Mixture of particles with high and low  $\text{Im}(m)$  could fit the observations.<sup>32</sup>

# Positive polarization vs. morphology at $m=1.313+0i$

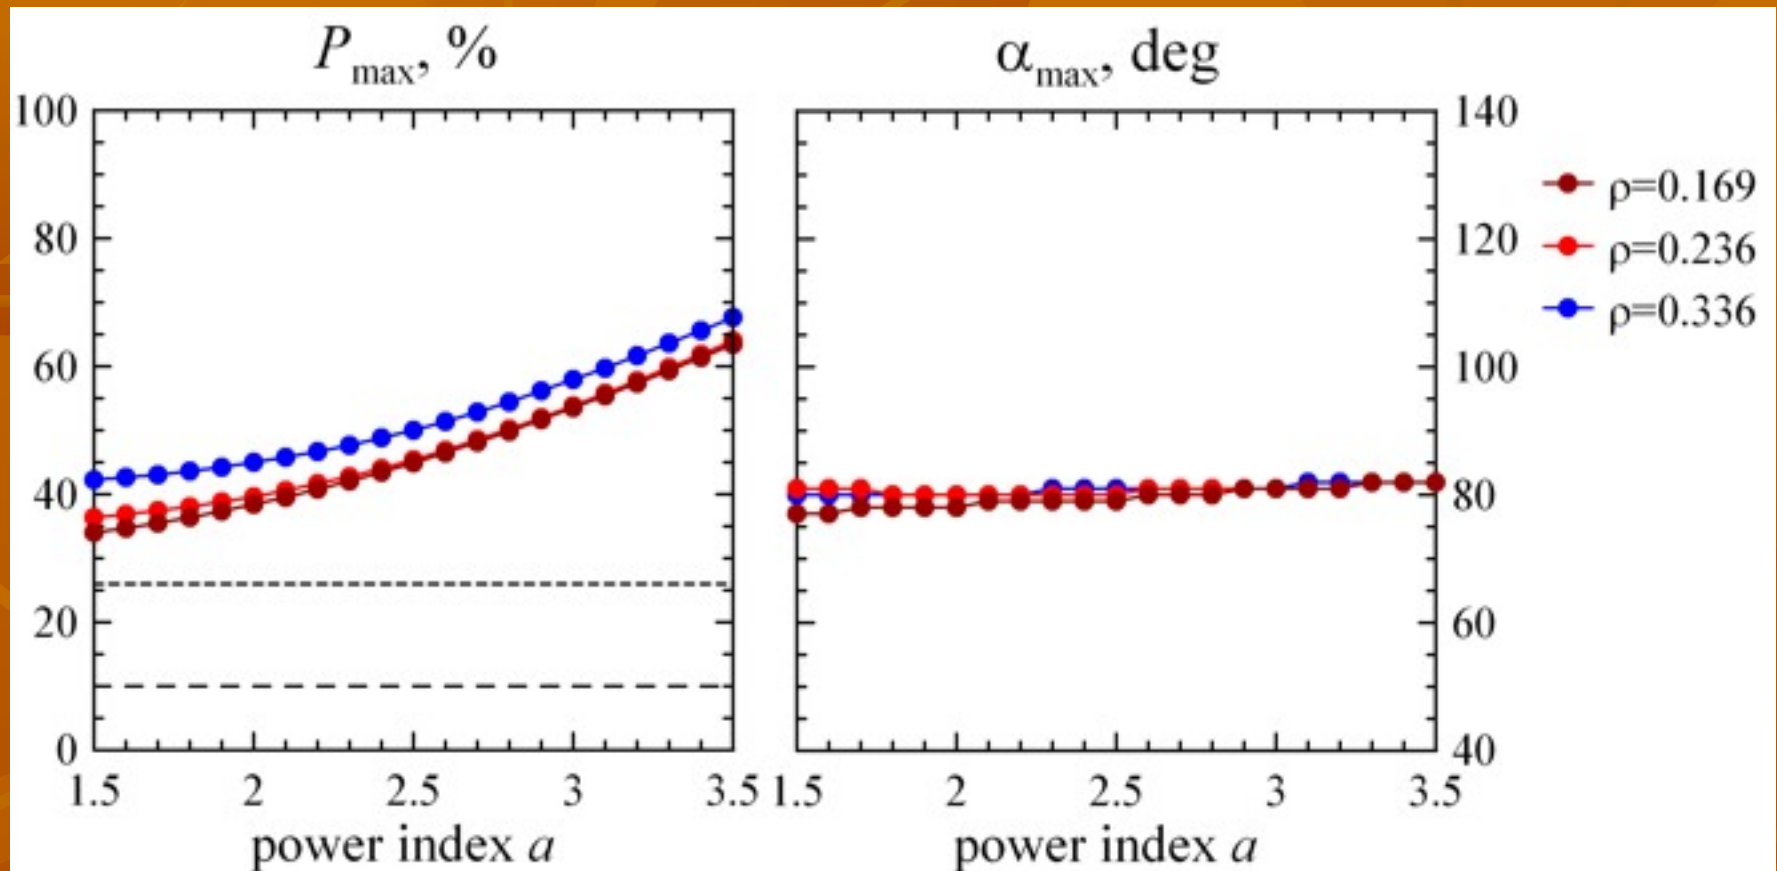

Particle morphology does not affect the positive polarization significantly. Nevertheless, potentially, such difference in  $P_{\max}$  could be detected.

# Positive polarization vs. morphology at $m=1.6+0.0005i$

Particle morphology does not affect the positive polarization significantly. Nevertheless, potentially, such difference in  $P_{\max}$  could be detected.

# Positive polarization vs. morphology at $m=1.5+0.1i$

Particle morphology does not affect the positive polarization significantly. Nevertheless, potentially, such difference in  $P_{\max}$  could be detected.

# Summary on the positive polarization

1. The positive polarization produced by single-scattering irregularly shaped particles is unambiguously dependent on  $\text{Im}(m)$ . It can be used to determine local excess for Mg-rich silicates and carbonaceous materials in a cometary coma.
2.  $P_{\text{max}}$  observed in comets cannot be reproduced with optically soft  $\text{Re}(m) < 1.3$  and highly absorbing  $\text{Im}(m) \geq 0.1$  materials. Thus, abundance of carbonaceous materials (with high  $\text{Im}(m)$ ) in comets should imply simultaneous presence of weakly absorbing cometary materials.
3. True morphology of irregular agglomerates produces only secondary effect on the positive polarization.

## 5. Estimation of the geometric albedo with the Umov effect

# What is the Umov effect?

N. Umov (1846-1915)

The brighter is a powder,  
the lower is its linear polarization

Umov, Phys. Zeits. 6, 674-676 (1905)

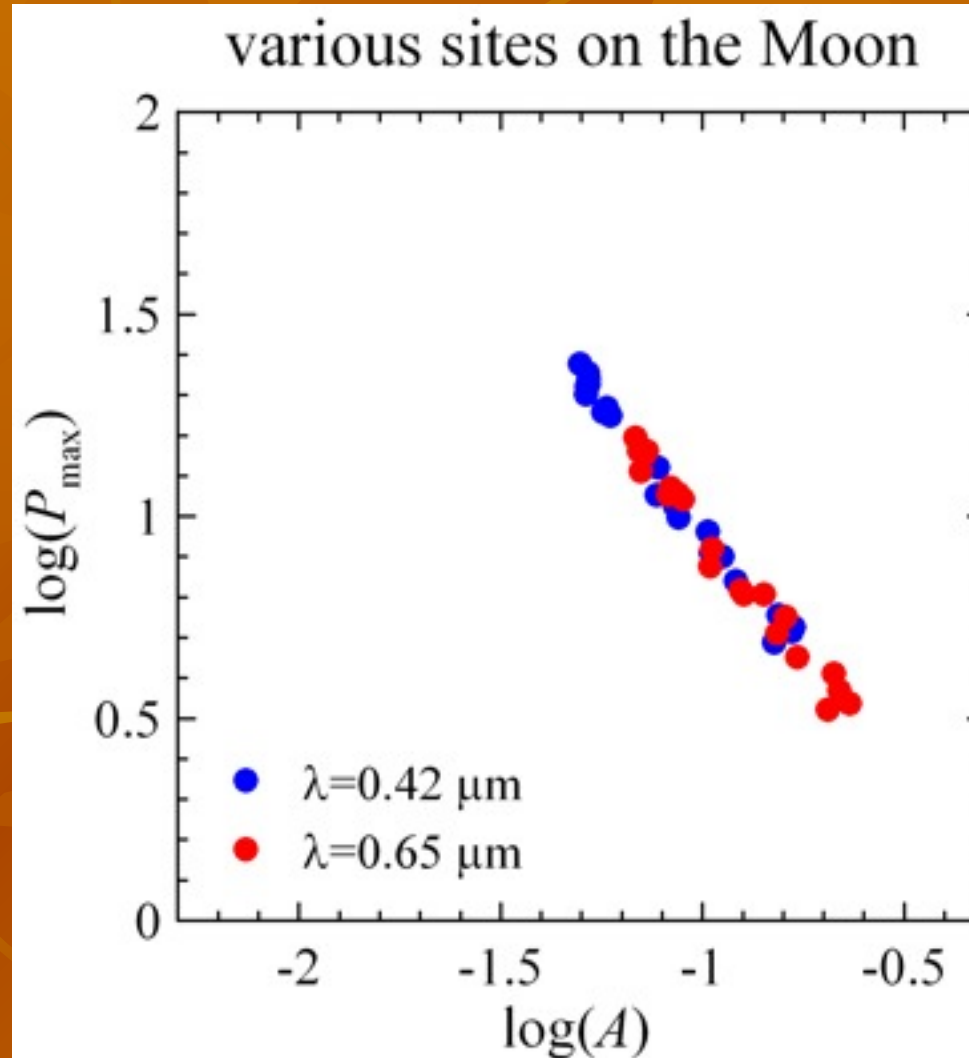

Origin of the effect

depolarization that is caused by  
multiple scattering in regolith

In 1960-1970, the qualitative law has been quantified as follows:

$\log(P_{\max})$  linearly depends on  $\log(A)$ .

# the Umov effect for the Moon

Shkuratov & Opanasenko, Icarus 99, 468-484 (1992)

# the Umov effect for single-scattering particles?

Why such extension could make sense:

- (1) The Umov effect holds for quite dark surfaces
- (2) In dark surfaces, single-scattering contributes substantially into the whole light scattering

Geometric albedo for the case of single particles:

$$A = (M_{11}(0)\pi) / (k^2 G)$$

Here,  $M_{11}(0)$  is the total intensity Mueller matrix element at backscattering,  $k$  – the wave number, and  $G$  – the geometric cross-section of the particle.

# A in comets from the Umov effect

Agglomerated debris particles  $\rho=0.236$

Haloes

Whole comets

$P_{\max} \approx 10\%$ :

$P_{\max} \approx 26\%$ :

$A = 0.11 - 0.21$

$A = 0.04 - 0.08$

# A in comets from the Umov effect

## Agglomerates with different morphology

Variation of agglomerate morphology produces rather small impact on the diagrams  $\log(A)$  vs.  $\log(P_{\max})$

1. Degree of linear polarization is an important source of information on dust in comets. Both, the negative and the positive polarization branches reveal dramatic dependence on the material absorption. Thus, they could be used for detection of time- and spatial variations in chemical composition.
2. Maximum of the positive polarization  $P_{\max}$  correlates with the geometric albedo  $A$  of target particles through the Umov effect. When applied to whole coma, it provides  $A=0.04-0.08$  that is well consistent with other methods. However, the Umov effect predicts also a substantial variation of  $A$  throughout coma. For instance, in the innermost part of coma, i.e., circumnucleus halo, it could be a few times higher as compared to whole coma  $A=0.11-0.21$ .
