# 1. Introduction

Radiative transfer model is a fundamental tool to clarify planetary environment

## Spectral analyses of radiation from a planet

which give us information about temperature and composition of its atmosphere

Estimate composition: e.g. Kreidberg et al., 2014

a high resolution spectral calculation is required

## Energy budget calculations

with which we can proceed to discuss such as circulation of an atmosphere and evolution of a planet

Habitable zone: e.g. Kopparapu et al., 2013

Planetary evolution: e.g. Hamano et al., 2013

a high speed calculation covering a wide spectral range is required

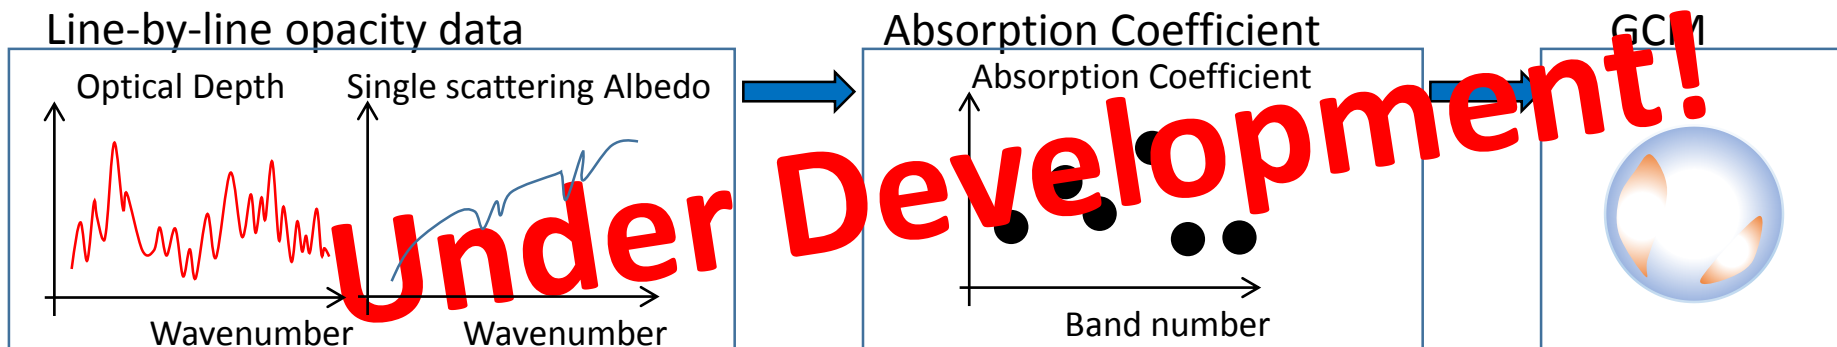

## 2. Model Overview

### 1. Line-by-line model

### 2. k-distribution model for GCM

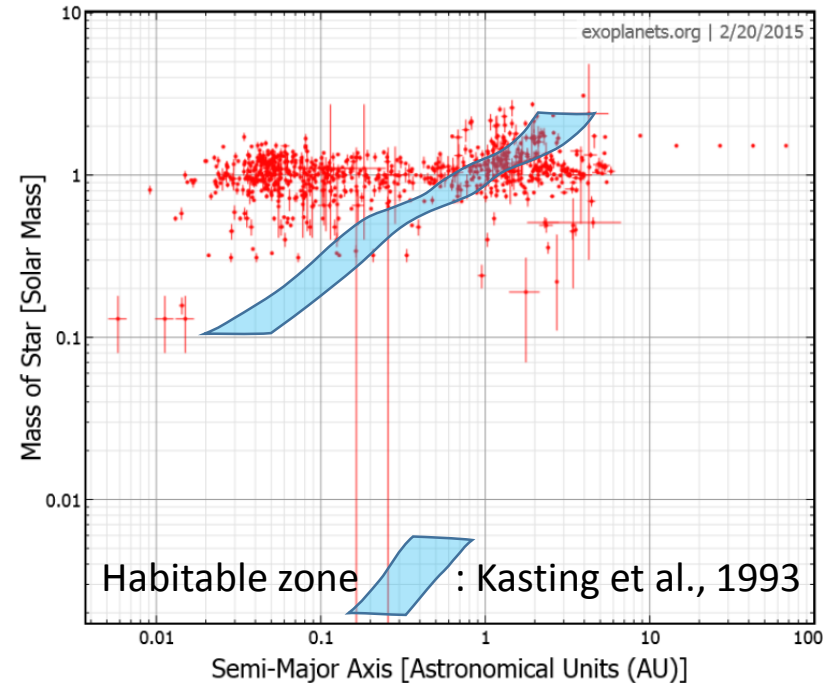

### 3. Application to exoplanets

## Tropopause of steam atmosphere and inner edge of habitable zone

### Inner edge of habitable zone:

1. Runaway greenhouse limit:  
net solar irradiance = radiation limit
2. Water loss limit:  
a planet has ocean as long as 4.6 billion yr.
  - Kasting+1993: 0.95AU
  - Kopparapu+2013: 0.99AU

*The model stratosphere was taken to be isothermal at 200K; this assumption has negligible effect on the runaway greenhouse limit but **may have a significant effect on the “water loss” limit.** (Kasting+1993)*

We are trying to estimate tropopause temperature by 1-D lime-by-line model.

# 3. Application to exoplanets

## Model & Setup

### Estimate of tropopause

Temperature profile  
H<sub>2</sub>O mixing ratio profile

Optical depth  
Single scattering albedo

Radiation budget  
Heating rate

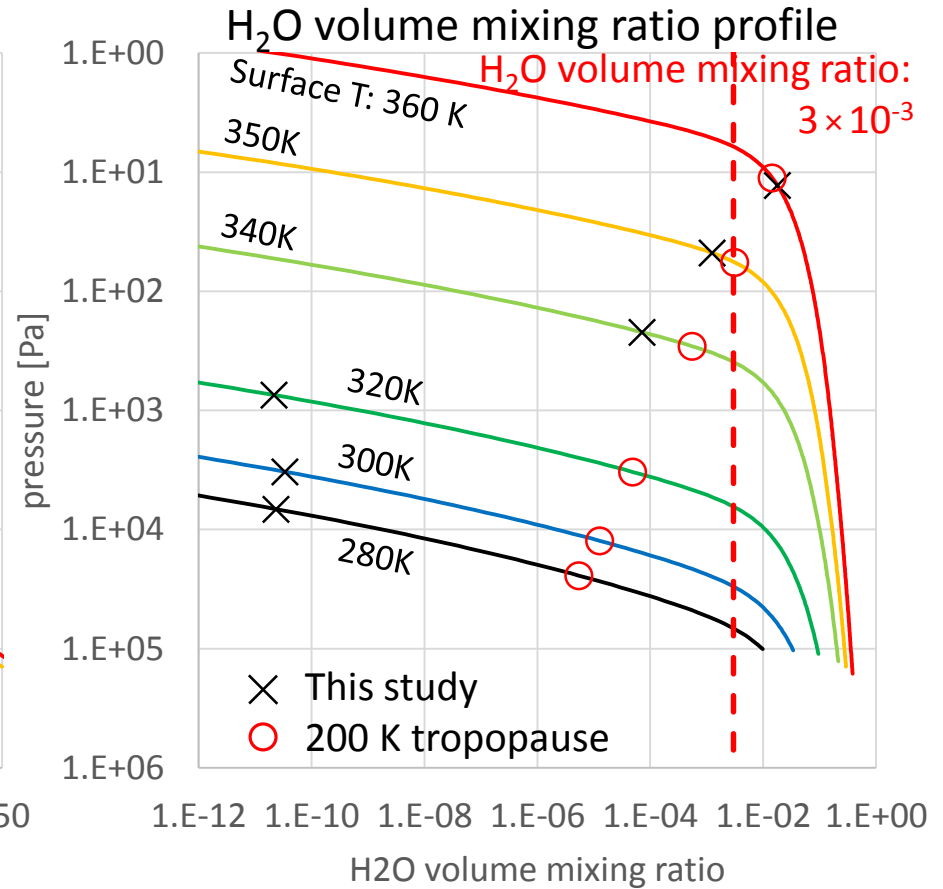

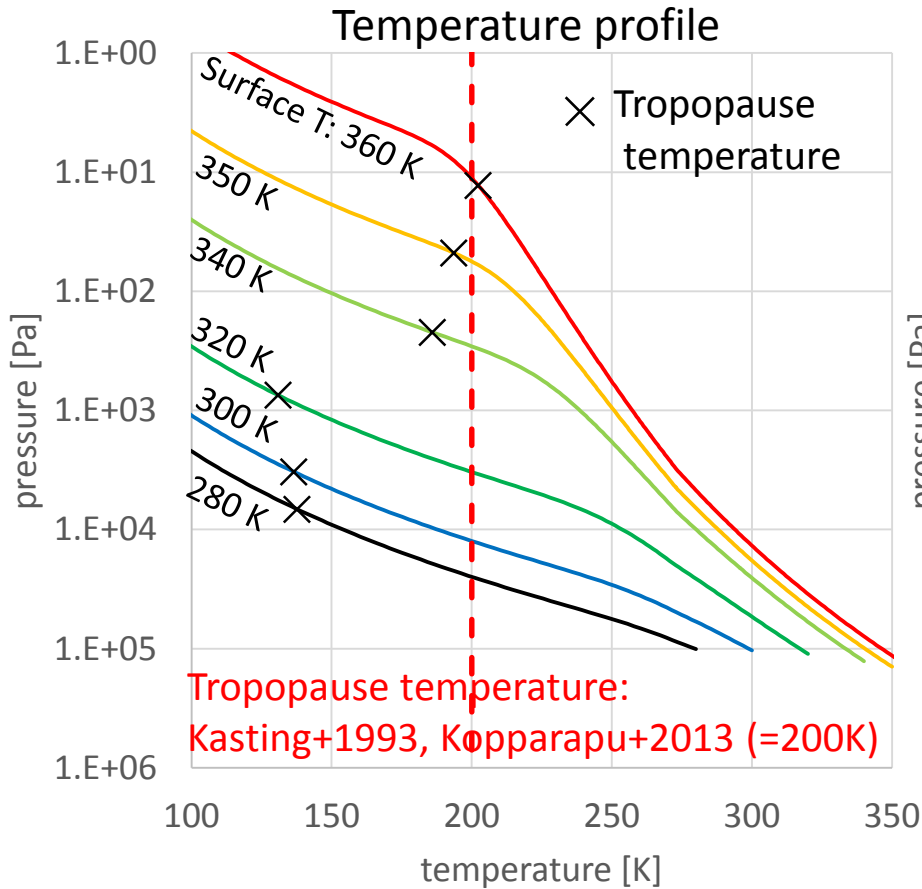

- H<sub>2</sub>O + non-absorption gas (10<sup>5</sup> [Pa])
- Convective atmosphere up to TOA
- Moist pseudoadiabatic lapse rate
- Surface temperature:  
280, 300, 320, 340, 350, 360 [K]

- Line absorption:  
HITRAN 2008
- Continuum absorption:  
MT\_CKD 2.5, Chan et al., 1993
- Rayleigh scattering cross section:  
Goldblatt et al., 2013

- Solar irradiance:  
5800[K] black body
- Surface albedo:  
0 – 3000cm<sup>-1</sup>: 0.0  
> 3000cm<sup>-1</sup>: 0.2
- Wavenumber range:  
0 – 100000cm<sup>-1</sup>

### 3. Application to exoplanets

## Results: Estimate of tropopause temperature & mixing ratio

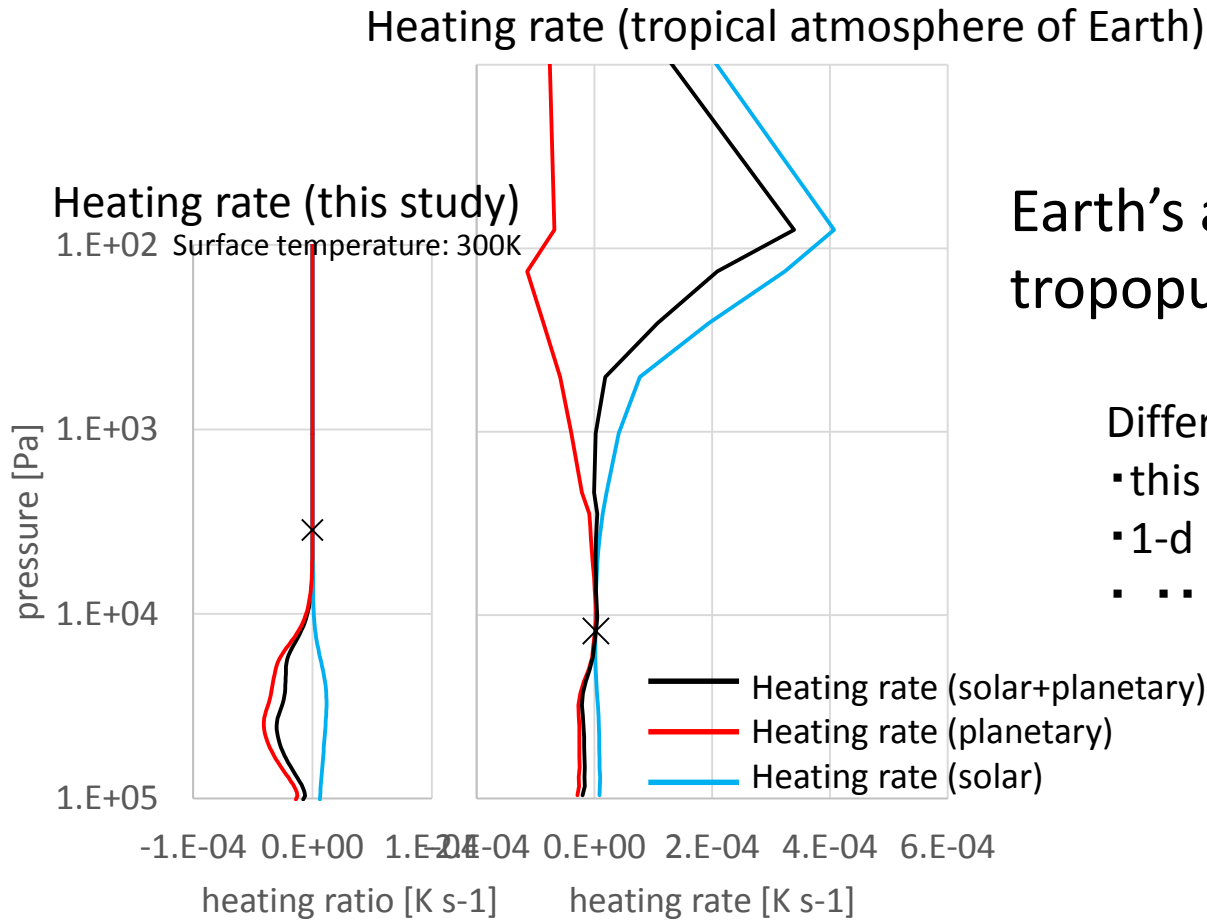

Water loss limit is estimated near the previous studies.

**We have been developing k-distribution model and trying to calculate 1-D radiative convective profiles.**

# 3. Application to exoplanets

## Comparison of Earth atmosphere

Earth's atmosphere has lower tropopause than this study.

Different points between both:

- this study is lack of O<sub>3</sub>
- 1-d model and 3-d Earth
- ..

# 3. Application to exoplanets

## Atmospheric evolution and tropopause level

### Atmospheric evolution

#### 1. General circulation is modified?

#### 2. Chemical radical is well mixed?

Solar radiation: NREL, 2000 ASTM Standard Extraterrestrial Spectrum Reference E-490-00

H<sub>2</sub>O: HITRAN2008, MT\_CKD2.5, Chan+1993

CO<sub>2</sub>: HITRAN2008, MT\_CKD2.5, Cairns&Samson 1966, Cook&Metzger 1964, Edward et al., 1953, Thompson et al., 1963

O<sub>3</sub>: HITRAN2008, MT\_CKD2.5

O<sub>2</sub>: Hudson 1971, Cook&Metzger 1964, Watanabe&Marmo 1956, Nagata&Todomatsu 1973

N<sub>2</sub>: Hudson 1971, Cook&Metzger 1964, Watanabe&Marmo 1956

## 4. Summary

- We have been developing a radiative transfer model for exoplanets.
  - Line-by-line model and k-distribution model for GCM (under development)
- The model is applied to exoplanet atmosphere.
  - We estimate tropopause temperature of convective atmosphere by 1-D line-by-line model.
  - Tropopause temperatures are lower than 200K as in surface temperature is lower than 340 K.
  - Water loss limit is estimated near the previous studies.
